pp: PRC 96,014907 2305.10750

AA: first results for: PRC107.054913 Strong 2020 - HFHF Taormina, Sept.28 – Oct. 4 2023

Why do we study J/ψ production in heavy-ion collisions?

 J/ψ mesons

- are a hard probe: test quark-gluon plasma from creation to hadronization
- no consistent microscopical theory available yet
- show quite different results for key observables at RHIC and LHC which are not fully understood yet:

J/ψ production in p+p collisions

How to describe a bound state like a c-cbar in QCD? It involves low momenta and needs non perturbative input → assumptions. Our approach: Wigner density formalism (as successful at lower energies)

Wigner Density Formalism

c-cbar interaction depends on relative p and r only, \rightarrow plane wave of CM Starting point: Wave function (w.f.) of the relative motion of state i: $|\Phi_i\rangle$

w.f. \rightarrow density matrix $|\Phi_i > < \Phi_i|$

Wigner density of $|\Phi_i \rangle$: $\Phi_i^W(\mathbf{r}, \mathbf{p}) = \int d^3 y e^{i\mathbf{p}\cdot\mathbf{y}} < \mathbf{r} - \frac{1}{2}\mathbf{y}|\Phi_i\rangle < \Phi_i|\mathbf{r} + \frac{1}{2}\mathbf{y}\rangle$. (close to classical phase space density) $\mathbf{R} = \frac{\mathbf{r}_1 + \mathbf{r}_2}{2}, \quad \mathbf{r} = \mathbf{r}_1 - \mathbf{r}_2,$ $\mathbf{P} = \mathbf{p}_1 + \mathbf{p}_2, \quad \mathbf{p} = \frac{\mathbf{p}_1 - \mathbf{p}_2}{2}.$

$$n_i(\mathbf{R}, \mathbf{P}) = \sum_{\text{all } c\bar{c} \text{ pairs}} \int \frac{d^3 r d^3 p}{((2\pi)^3} \Phi_i^W(\mathbf{r}, \mathbf{p}) \prod_{\text{all other particles}} \int \frac{d^3 r_j d^3 p_j}{(2\pi)^{3(N-2)}} \rho_N^W(\mathbf{r}_1, \mathbf{p}_1 \dots \mathbf{r}_N, \mathbf{p}_N)$$

The results are obtained using a relativ. formulation

pp: In momentum space given by tuned PYTHIA In coordinate space $\sim r^2 \exp\left(-\frac{r^2}{2\delta^2}\right)$ $\delta^2 = \langle r^2 \rangle/3 = 4/(3m_c^2)$

Wigner Density Formalism

The Wigner density of the state $|\Phi_i\rangle$ is different for S and P states. Simplest possible (harmonic oscillator) parametrization:

$$\Phi_{S}^{W}(\mathbf{r}, \mathbf{p}) = 8 \frac{D}{d_{1}d_{2}} exp\left[-\frac{r^{2}}{\sigma^{2}} - \sigma^{2}p^{2}\right] \qquad \Phi_{P}^{W}(\mathbf{r}, \mathbf{p}) = \frac{16}{3} \frac{D}{d_{1}d_{2}} \left(\frac{r^{2}}{\sigma^{2}} - \frac{3}{2} + \sigma^{2}p^{2}\right) exp\left[-\frac{r^{2}}{\sigma^{2}} - \sigma^{2}p^{2}\right] \qquad D: \text{degeneracy of } \Phi$$

Where σ reproduces the rms radius of the vacuum c cbar state

D : degeneracy of Φ d₁ : degeneracy of c d₂ : degeneracy of cbar $\sigma \sim$ radius of Φ

The tuned PYTHIA reproduces FONLL charm quark calculations but J/Ψ multiplicity depends in addition on the ccbar correlation (not known in FONLL)

pp: comparison with PHENIX and ALICE data

Wigner density based model reproduced pp J/ Ψ data

pp: comparison of Y(nS) with CMS/ALICE data

Wigner density approach works also for Y(nS)

AA collisions

Primary production of J/Ψ in AA

Without the formation of a QGP we expect a (large) enhancement of the J/ψ production because c and cbar from different NN vertices can form a J/ψ .

but experiments show suppression

Reason: J/ψ production in HI collisions is a very complex process

The different processes which influence the J/ ψ yield

- Creation of heavy quarks (shadowing)
- J/ψ are first unstable in the quark gluon plasma and are created later
- c and cbar interact with the QGP
- c and cbar interact among themselves (← lattice QCD)
- If QGP arrives at the dissociation temperature T_{diss} , stable J/ ψ are possible
- J/ψ creation ends when the QGP hadronizes
- J/ψ can be further suppressed or created by hadronic interaction (task for the future → Torres-Rincon)
- There are in addition J/ψ from the corona (do not pass the QGP)

Our model follows the time evolution of all c and cbar quarks,

is based, as our pp calculation, on the Wigner density formalism assumes that

all c and cbar interact with QGP as those observed finally as D-mesons

all c and cbar interact among themselves

uses EPOS2 to describe the expanding QGP

HQ interactions with QGP verified by D meson results

D mesons test the energy loss and v_2 of heavy quarks in a QGP energy loss tests the initial phase v_2 the late stage of the expansion Two mechanisms : collisional energy loss: PRC78 (2008) 014904 radiative energy loss: PRD89 (2014) 074018

EPOS4HQ reproduces dN/dp_T , R_{AA} and v_2 quite well \rightarrow Heavy quark dynamics in QGP medium under control

J/ψ dynamics in heavy ion collisions

Starting point: von Neumann equation for the density matrix of all particles $\partial \rho_N / \partial t = -i[H, \rho_N]$ with $H = \sum_i K_i + \sum_{i>j} V_{ij}$ $P^{\Phi}(t) = \operatorname{Tr}[\rho^{\Phi} \rho_N(t)]$ with $\rho^{\Phi} = |\Psi^{\Phi} \rangle \langle \Psi_{\Phi}|$ gives the multiplicity of Φ at time t

This is the solution if we would know the quantal $\rho_N(t)$ $\rho_N(t)$ is unknown so we follow BUU,QMD ...

 $\rho_N = < W_N^{c(classical)} >$

and replace $P^{\Phi}(t)$ by the integration over the rate:

$$\Gamma^{\Phi}(t) = \frac{dP^{\Phi}}{dt} = \frac{d}{dt} \operatorname{Tr}[\rho^{\Phi}\rho_{N}(t)] \qquad P^{\Phi}(T) = \int_{0}^{T} \Gamma^{\Phi}(t) dt$$

We assume that heavy quarks and QGP partons interact by collisions only:

$$\Gamma^{\Phi} = Tr(\rho^{\Phi} d\rho^{N}(t)/dt) = -iTr(\rho^{\Phi}[H, \rho^{N}(t)]) = -iTr(\rho^{\Phi}[U_{12}, \rho^{N}])$$
$$U_{12} = \sum_{j \leq 3} (V_{1j} + V_{2j})$$

elastic HQ interactions with the QGP

 \frown

The interaction between HQ and q and g is described by Born type diagrams

$$\frac{d\sigma_F}{dt} = \frac{\mathbf{g^4}}{\pi (s - M^2)^2} \Big[\frac{(s - M^2)^2}{(t - \kappa \mathbf{m_D^2})^2} + \frac{s}{t - \kappa \mathbf{m_D^2}} + \frac{1}{2} \Big] \quad \bigoplus_{\Theta \Theta \Theta}^{\Theta \Theta} \mathcal{F}^{\mathsf{V(r)} \sim \frac{\exp(-m_e r)}{r}}$$

q/g is randomly chosen from a Fermi/Bose distribution with the hydro cell temperature

coupling constant and infrared screening are input

Peshier NPA 888, 7 based on universality constraint of Dokshitzer If t is small (<<T) : Born has to be replaced by a hard thermal loop (HTL) approach For t>T Born approximation is (almost) ok

(Braaten and Thoma PRD44 1298,2625) for QED: Energy loss indep. of the artificial scale t* which separates the regimes Extension to QCD (PRC78:014904)

к ≈ 0.2

Inelastic Qq \rightarrow Qqg collisions

M^{SQMD} in light cone gauge

In the limit $\sqrt{s} \rightarrow \infty$ the radiation matrix elements factorize in

$$M_{tot}^2 = M_{elast}^2 \cdot P_{rad}$$

 k_t , ω = transv mom/ energy of gluon E = energy of the heavy quark

Open heavy flavor results in pp and AA from EPOS4

J/ψ creation in heavy ion collisions

 $\Gamma^{\Phi}(t)$ expressed in Wigner and classical phase space density:

$$\Gamma^{\Phi}(t) = \frac{dP^{\Phi}(t)}{dt} = \frac{d}{dt} Tr[\rho^{\Phi}, \rho_N(t)] \approx \frac{d}{dt} \prod \frac{d^3 r_i d^3 p_i}{(2\pi)^{3N}} W^{\Phi}(\mathbf{r}, \mathbf{p}) W^c(\mathbf{r_1}, \mathbf{p_1}, \dots \mathbf{r_N}, \mathbf{p_N})$$

If the collisions are point like in time and if $W^{\Phi}(\mathbf{r}_1, \mathbf{r}_2, \mathbf{p}_1, \mathbf{p}_2)$ is time independent (1,2 are charm quark, n=number of collision of i and j, $t_{ij}(n)$ =time of n-th collision of ij) :

J/ψ creation in heavy ion collisions

Lattice calc: $W^{\Phi}(\mathbf{r}_1, \mathbf{r}_2, \mathbf{p}_1, \mathbf{p}_2)$ depends on the temperature and hence on time

This creates an additional rate, called local rate

$$\Gamma_{loc} = (2\pi\hbar)^3 \int d^3r d^3p \ W_{Q\bar{Q}}(\mathbf{r},\mathbf{p},t) \dot{W}_{\Phi}(\mathbf{r},\mathbf{p},T(t)).$$

Final multiplicity of J/Ψ in heavy-ion coll with a dissociation temperature

$$P(t) = P^{prim}(t_{init}) + \int_{t_{init}}^{t} [\Gamma_{coll}(t') + \Gamma_{loc}(t')]dt' \rightarrow P(t \rightarrow \infty) = \text{asympt. multiplicity}$$

Interaction of c and cbar in the QGP

V(r) = attractive potential between c and cbar (PRD101,056010) We work with

$$\begin{aligned} \mathcal{L} &= -\gamma^{-1}mc^2 - V(r) \quad H = \sqrt{m^2 + p_r^2 + \frac{p_\theta^2}{r^2}} + V(r) \\ p^2 &= p_r^2 + p_\theta^2/r^2 \\ \gamma^{-1} &= \sqrt{1 - v^2/c^2} \end{aligned}$$

Has to be improved to describe high $p_T \; J / \Psi$

Position and momentum of each c-cbar pair evolve according to Hamiltons equations

c-cbar potential keeps the quarks together \rightarrow increases multiplicity

Influence of the Corona

EPOS 2 show two classes of particles of initially produced particles:

- Core particles which become part of QGP
- Corona particles from the surface of the interaction zone (energy density too low, no collision after production → like pp) importent for high pt and for v2

Confirmed by centrality dependence of multiplicity

For elementary particles it is easy to define corona and core particle (2306.10277)

For J/ ψ mesons we use as working description: Corona J/ ψ are those where none of its constituents suffers from a momentum change of q > q_{thres}. Larger q would destroy a J/ ψ .

Comparison with ALICE data

Caution: excited states decay, b decay and hadronic rescattering not in yet

influence of the corona

Comparison with ALICE data

Our approach and open quantum systems

Von Neuman eq.

$$\partial \rho_N / \partial t = -\frac{i}{\hbar} [H, \rho_N] \qquad H = H_{1,2} + H_{N-2} + U_{1,2} \qquad U_{1,2} = \Sigma_j V_{1,j} + \Sigma_j V_{2,j}$$

Prob. to find quarkonium $P^{\Phi}(t) = \operatorname{Tr}[\rho^{\Phi}\rho_{N}(t)]$ with $[\rho^{\Phi}, H_{1,2}] = 0$ $[\rho^{\Phi}, H_{N-2}] = 0$ Quarkonium rate: $\frac{dP^{\Phi}(t)}{dt} = \Gamma^{\Phi}(t) = \frac{-i}{\hbar}Tr[\rho^{\Phi}[U_{1,2}, \rho_{N}(t)]]$

$$\partial \rho_N(t) / \partial t = -\frac{i}{\hbar} \Sigma_j [K_j, \rho_N(t)] - \frac{i}{\hbar} \Sigma_{k>j} [V_{jk}, \rho_N(t)].$$

Interaction: coll. heavy quarks - partons:

$$= -\frac{i}{\hbar} \Sigma_{k>j} [V_{jk}, \rho_N(t)] \equiv \langle \Sigma_{k>j} \Sigma_n \delta(t - t_{jk}(n)) \\ \cdot (W_N^c(\{\mathbf{r}\}, \{\mathbf{p}\}, t + \epsilon) - W_N^c(\{\mathbf{r}\}, \{\mathbf{p}\}, t - \epsilon)) \rangle.$$

yields

$$\frac{dP^{\Phi}(t)}{dt} = \Gamma^{\Phi}(t) = h^3 \frac{d}{dt} \int \prod_j^N d^3r_j d^3p_j W^{\Phi}_{12} W^c_N(t) = h^3 \int \prod_j^N d^3\mathbf{r}_j d^3\mathbf{p}_j \ W^{\Phi}_{12} \frac{\partial}{\partial t} W^c_N(t)$$

Lindblad eq. (open quantum systems) in the quantal Brownian motion regime

$$\frac{d}{dt}\rho(t) = -i\left[\frac{p^2}{M} + \Delta H, \rho\right] + \sum_n \int \frac{d^3k}{(2\pi)^3} \left[C_n(\vec{k})\rho C_n^{\dagger}(\vec{k}) - \frac{1}{2}\left\{C_n^{\dagger}(\vec{k})C_n(\vec{k}), \rho\right\}\right]$$

Miura, Akamatsu , 2205.15551

Summary

We presented a new approach for quarkonia production in pp collision based on the Wigner density matrix It describes the y and p_T dependence of the spectra for J/ Ψ , χ and Y from RHIC to LHC

Based on these results we presented a new microscopic quantal approach for J/ \square production in AA which follows each c and cbar from creation until detection as J/ ψ

based on $\partial \rho_N / \partial t = -i[H, \rho_N]$ (no rate equation, no Fokker Planck eq., no thermal assumptions)

- c and cbar are created in initial hard collisions (controlled by pp data)
- when entering the QGP J/ψ become unstable
- c and cbar interact by potential interaction (lattice potential)
 c and cbar interact by collisions with q,g from QGP
- when T < T_{diss} = 400 MeV J/ ψ can be formed (and later destroyed)
- formation described by Wigner density formalism (as in pp)
- > Including corona J/ \mathbb{R} , preliminary results agree reasonably with ALICE data for R_{AA} as well as for v_2 .
- The later production (over) compensates the expected multiplicity increase (with respect to pp) due to c and cbar from different vertices
- > We observe an enhancement of $R_{AA}(J/\Psi)$ at low p_T at LHC, as seen experimentally

Outlook

a lot remains to be done:

- Follow the color structure, excited states
- Relativistic kinematics,
- J/ψ interaction in the hadronic expansion reduced cross section of preformed J/ψ (r < λ_{gluon}) with QGP partons (dipole cross section)
