# Outline

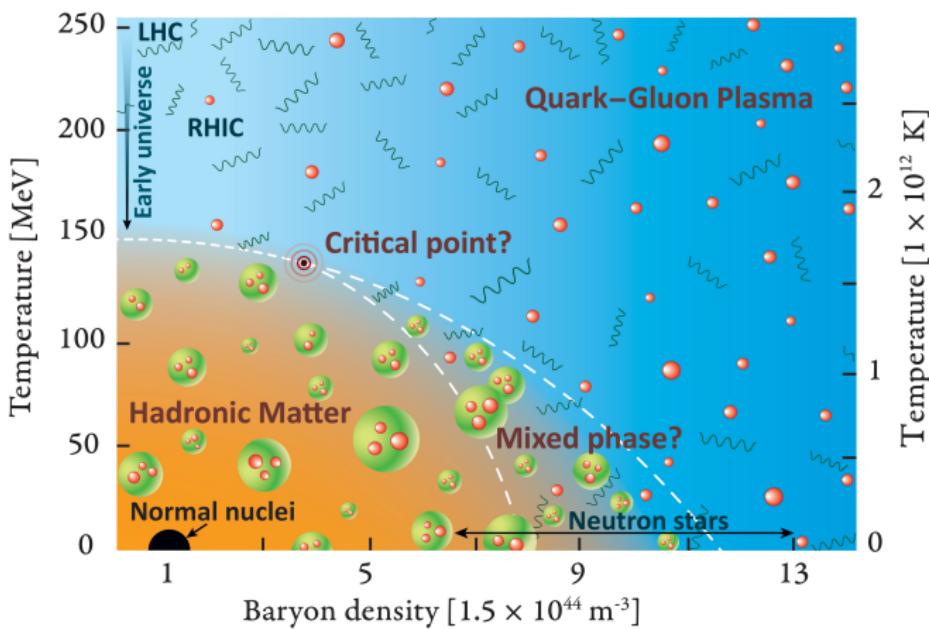

The QCD Phase Diagram

Chiral Fluid Dynamics

Multiplicity Ratios

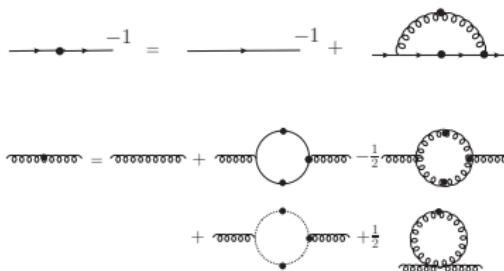

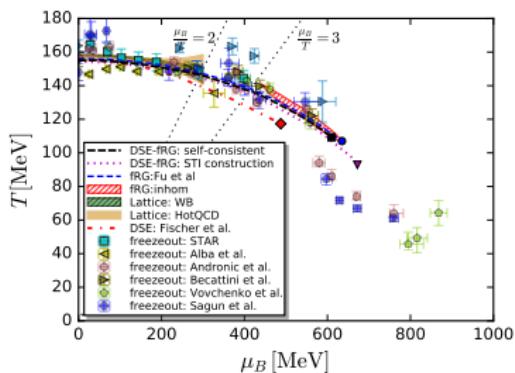

Summary

# The QCD Phase Diagram

# First principle calculations

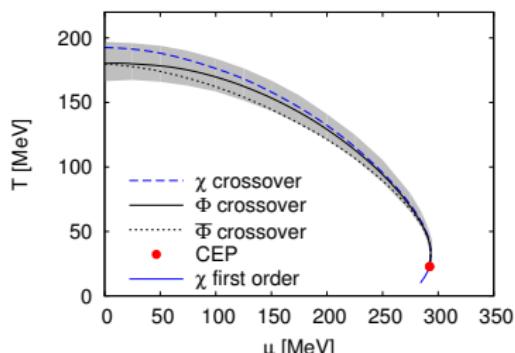

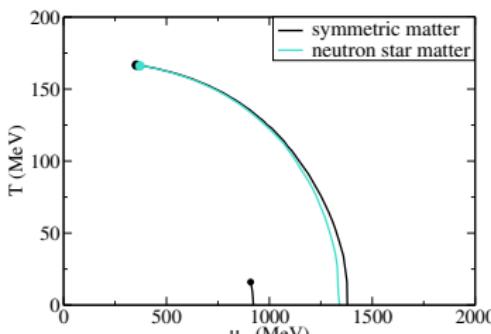

- Partition function  $\mathcal{Z}$  on a lattice (sign problem for finite  $\mu$ )
- Solve Dyson-Schwinger equations

(Gao, Pawłowski, Phys. Lett. B 820, 2021)

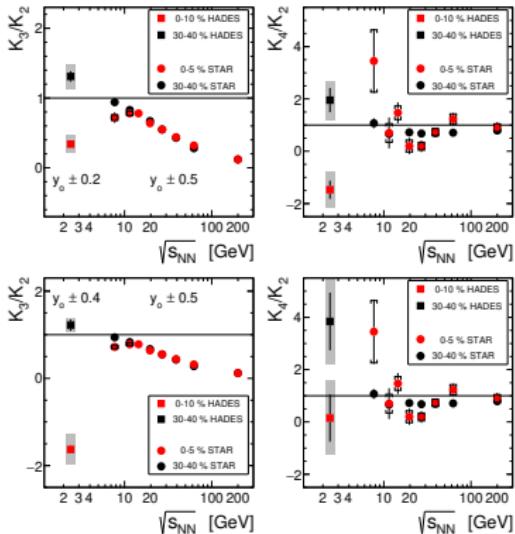

# Effective Models

- Start with (chiral) symmetry, sigma, NJL model
- Extension with Polyakov loop, baryonic degrees of freedom
- Existence/location of CP not universal

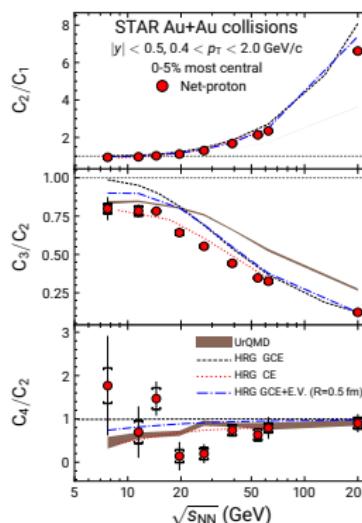

(Herbst, Pawłowski, Schaefer, Phys. Lett. B **696**, 2011)(Dexheimer, Schramm, Phys. Rev. C **81**, 2010)

# Critical Point - Signals and Observables

## 1. Higher order cumulants: HADES and STAR data

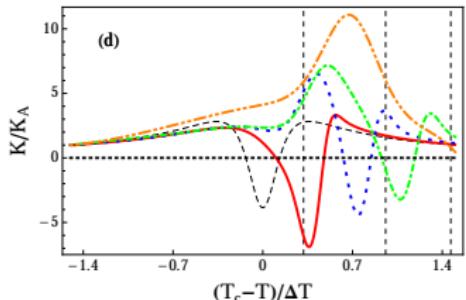

(HADES coll., Phys. Rev. C 102, 2020)

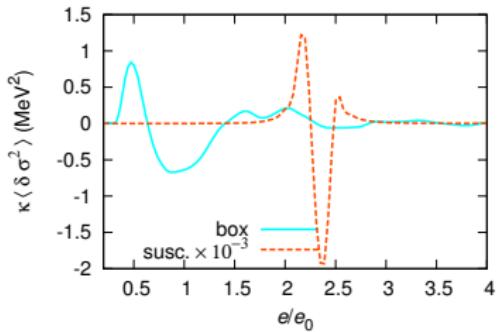

(STAR coll., Phys. Rev. C 104, 2021)

# Critical Point - Signals and Observables

## 2. Nonequilibrium effects

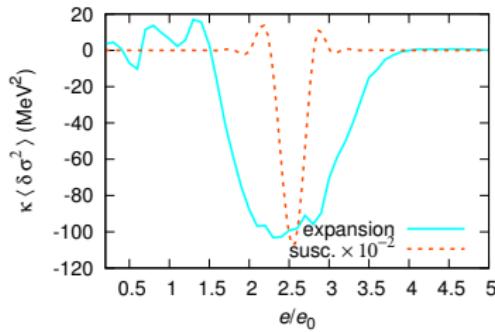

(Mukherjee, Venugopalan, Yin, Phys. Rev. C 92, 2015)

Cumulants are influenced by:

- Dependence on  $\xi$
- Relaxation time
- Inhomogeneities

(CH, Nahrgang, Bleicher et al., EPJ A54, 2018)

# Critical Point - Signals and Observables

- Determine cumulants of the 0-mode of the sigma field at freeze-out

$$\sigma_V = \int_V d^3x \sigma(x) = \sigma V$$

- Net-proton number fluctuations from Poisson plus critical fluct.

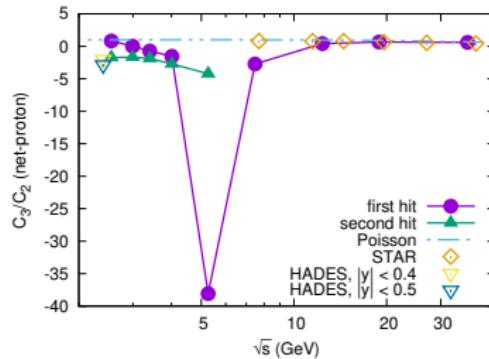

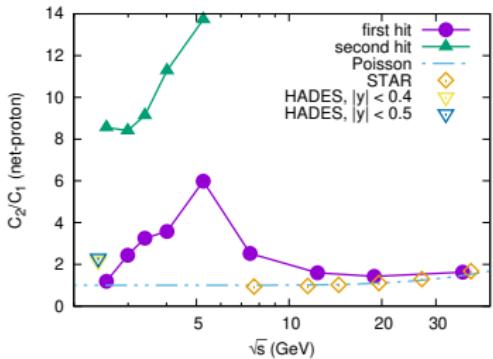

$$\delta N = \delta N^0 + V g \delta \sigma d \int \frac{d^3 p}{(2\pi)^3} \frac{\partial n_p}{\partial m}$$

- Relate net-proton to sigma cumulants

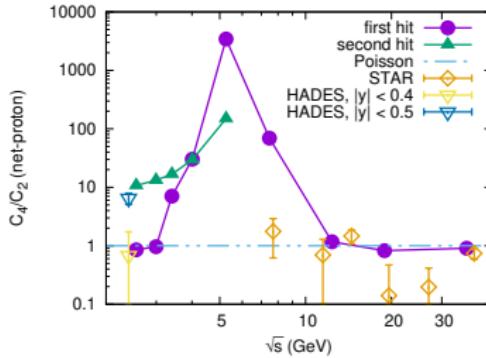

$$\langle (\delta N)^4 \rangle_c = \langle N \rangle + \langle \sigma_V^4 \rangle_c \left( \frac{g d}{T} \int \frac{d^3 p}{(2\pi)^3} \frac{n_p}{\gamma} \right)^4 + \dots,$$

(Stephanov, Phys. Rev. Lett. **107**, 2011)

# Critical Point - Signals and Observables

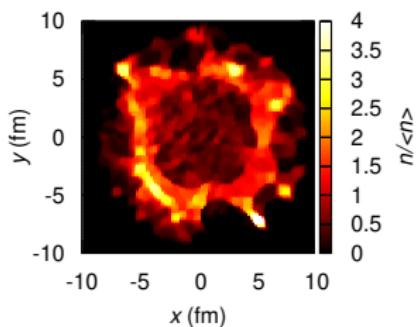

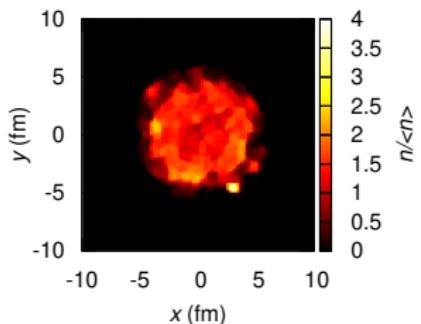

- Poisson baseline approached for large  $\sqrt{s}$
- Strongly enhanced cumulants near spinodal line
- FOPT allows for wider range of cumulants

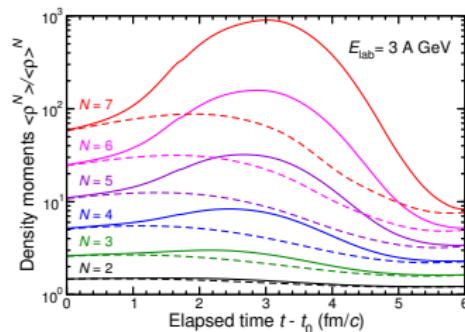

# First-order Phase Transition - Signals and Observables

## 1. Nonequilibrium effects: Spinodal instabilities

- Formation of Metastable phase
- Dynamical fragmentation
- Non-statistical multiplicity fluctuations
- Signal in momentum space?

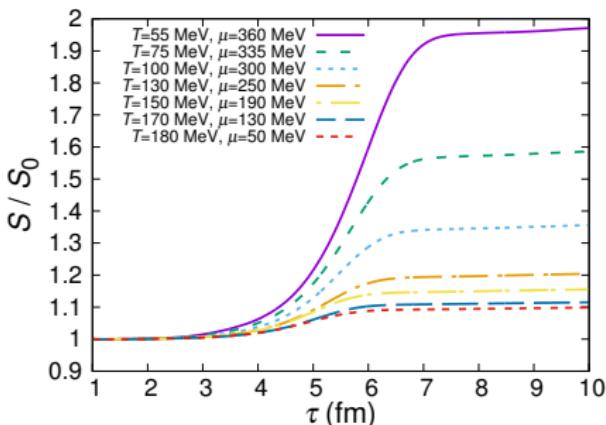

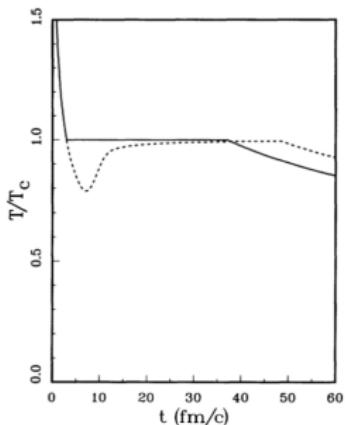

(CH, Nahrgang et al., Nucl. Phys. A 925, 2014)

(Steinheimer, Randrup, Phys. Rev. Lett. 109, 2012)

# First-order Phase Transition - Signals and Observables

## 2. Delayed Expansion

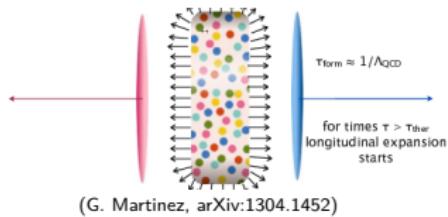

- Thermal radiation, dileptons
- Hanbury-Brown-Twiss Interferometry
- Generation of **Extra entropy** from nonequilibrium phase transition

(Csernai, Kapusta, Phys. Rev. Lett. **69**, 1992)(CH, Kittiratpattana et al., Phys. Lett. B **790**, 2019)

# N $\chi$ FD

## Nonequilibrium Chiral Fluid Dynamics (N $\chi$ FD)

- Nonequilibrium dynamics of  $\sigma$
- Fluid dynamic expansion
- damping and stochastic noise

$$\ddot{\sigma} + \eta \dot{\sigma} + \frac{\delta \Omega}{\delta \sigma} = \xi$$

$$\dot{e} = -\frac{e + P}{\tau} + \left( \frac{\delta \Omega}{\delta \sigma} + \eta \dot{\sigma} \right) \dot{\sigma}, \quad \dot{n} = -\frac{n}{\tau}$$

(CH, Kittiratpattana, Kobdaj, Limphirat, Yan, Nahrgang, Steinheimer, Bleicher, Phys. Lett. B **790**, 2019)

$$\mathcal{L} = \bar{q} (i \gamma^\mu \partial_\mu - g \sigma) q + \frac{1}{2} \partial_\mu \sigma \partial^\mu \sigma - U(\sigma)$$

Lagrangian of the quark-meson model

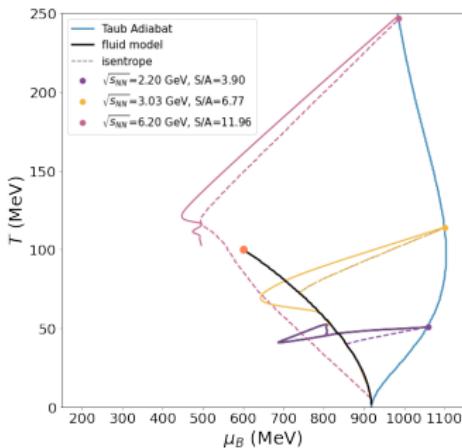

# Initial Conditions

- Realistic initial conditions
- 1D shock wave solution  
(Rankine-Hugoniot-Taub adiabat)

$$(P_0 + \varepsilon_0)(P + \varepsilon_0)n^2 = (P_0 + \varepsilon)(P + \varepsilon)n_0^2$$

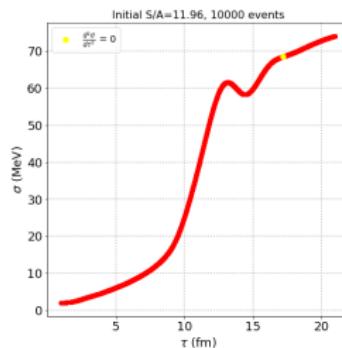

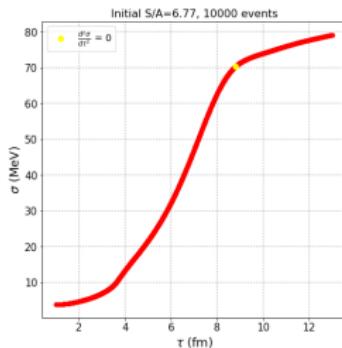

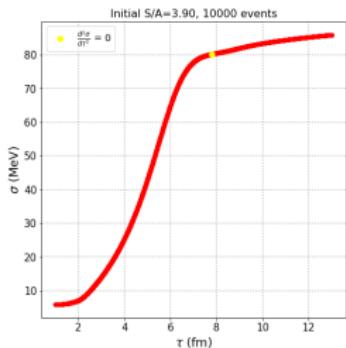

- Relate collision energy from compression:

$$\gamma^{\text{CM}} = \frac{\varepsilon n_0}{\varepsilon_0 n}, \quad \gamma^{\text{CM}} = \sqrt{\frac{1}{2} \left( 1 + \frac{E_{\text{lab}}}{m_N} \right)}$$

(Bumnedpan, CH, JS, MB, Phys. Lett. B **835**, 2022)

# "Freeze-out" condition

Test different freeze-out criteria depending on the evolution of  $\sigma$

- Freeze-out at constant value of  $\sigma = 70$  MeV
- Freeze-out at "end" of the rapid transition,  
i.e.  $d^2\sigma/d\tau^2 = 0$

## Fit to chemical freeze-out curves

- Use two parametrized freeze-out curve obtained from hadron multiplicity ratios

$$T_{\text{freeze}}(\mu_B) = a - b\mu_B^2 - c\mu_B^4$$

- Parameter set A:

$$a = 0.157 \text{ GeV}, b = 0.087 \text{ GeV}^{-1} \text{ and } c = 0.092 \text{ GeV}^{-3}$$

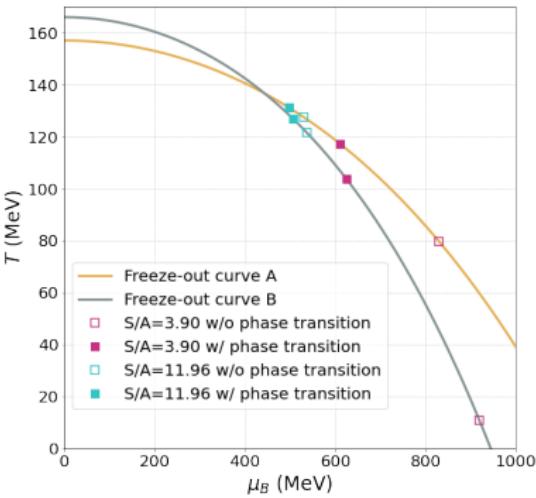

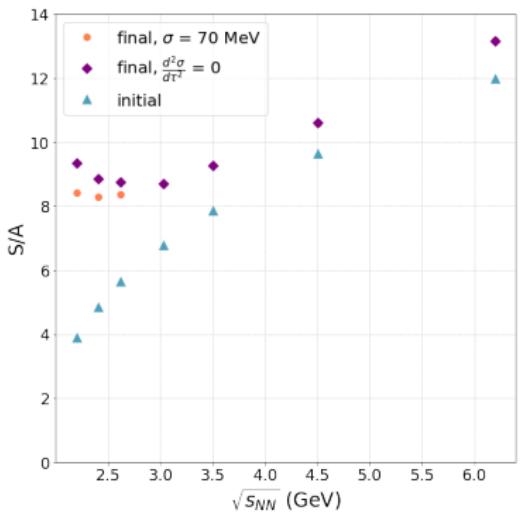

(Vovchenko, Begun, Gorenstein, Phys. Rev. C 93, 2016)

- Parameter set B:

$$a = 0.166 \text{ GeV}, b = 0.139 \text{ GeV}^{-1} \text{ and } c = 0.053 \text{ GeV}^{-3}$$

(Cleymans, Oeschler, Redlich, Wheaton, Phys. Rev. C 73, 2006)

# Entropy per baryon number

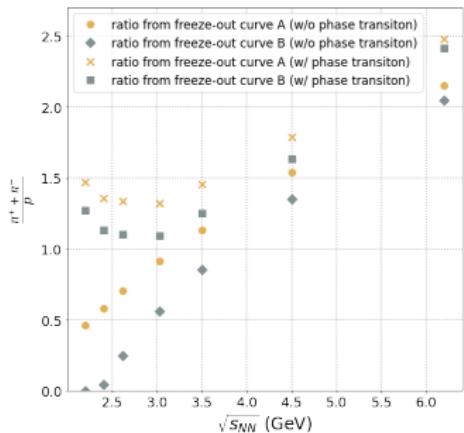

(Bumnedpan, CH, JS, MB, Phys. Lett. B 835, 2022)

- Qualitatively similar results for  $S/A$ , slight deviations at low  $\sqrt{s}$
- Fit to freeze-out curves using Thermal-FIST HRG toolkit

(Vovchenko, Stoecker, Comput. Phys. Commun. 244, 2019)

# Pion-to-proton ratio

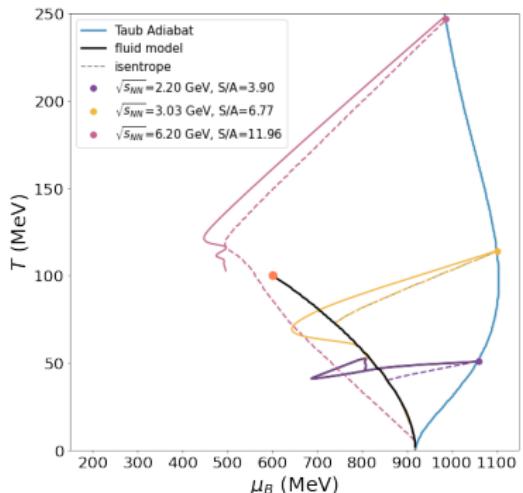

- Pion-to-proton ratio as observable for  $S/A$
- FOPT scenario leads to increase at low  $\sqrt{s}$
- In the model: Initial state always in restored phase
- Realistically: Jump in  $\pi/p$  at onset of chiral PT, around  $\sim 3$  GeV

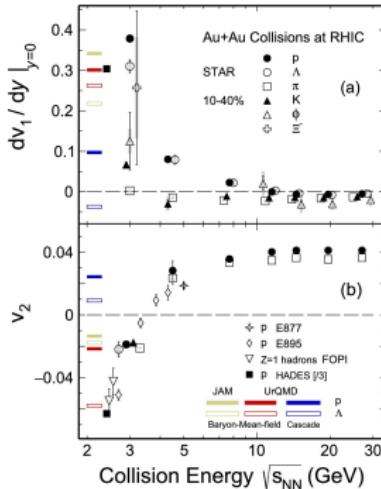

(STAR, Phys. Lett. B 827, 2022)

(Bumnedpan, CH, JS, MB, Phys. Lett. B 835, 2022)

## Caveats and what to look for

(Bummedpan, CH, JS, MB, Phys. Lett. B 835, 2022)

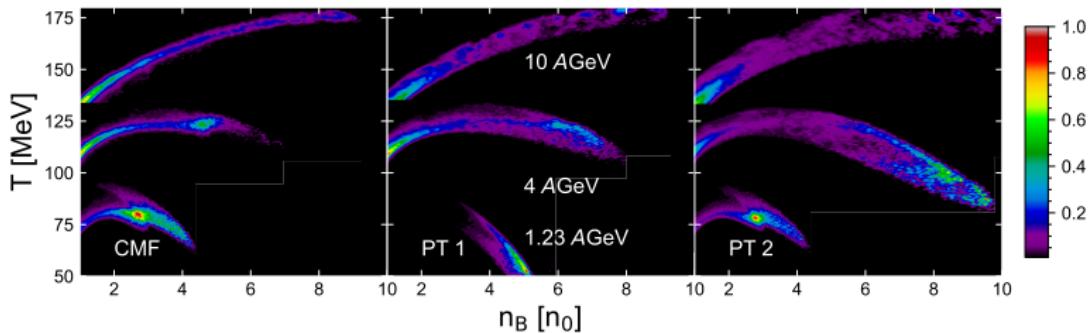

(STAR coll., Phys. Lett. B 827, 2022)

- Model caveat: Initial state always in the restored phase
- Measurements of  $v_1$ ,  $v_2$  at STAR suggest dominance of baryons for  $\sqrt{s_{NN}} \lesssim 3 \text{ GeV}$
- Expect jump in  $\pi/p$  at onset of chiral PT around  $\sim 3 \text{ GeV}$

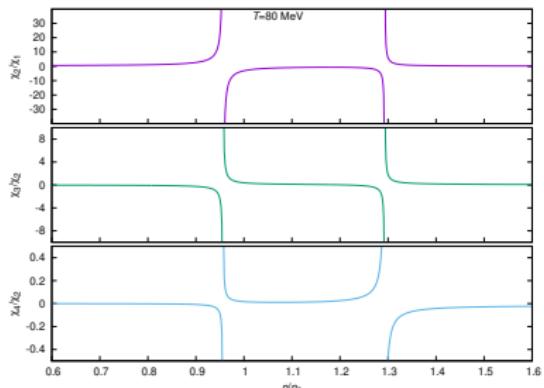

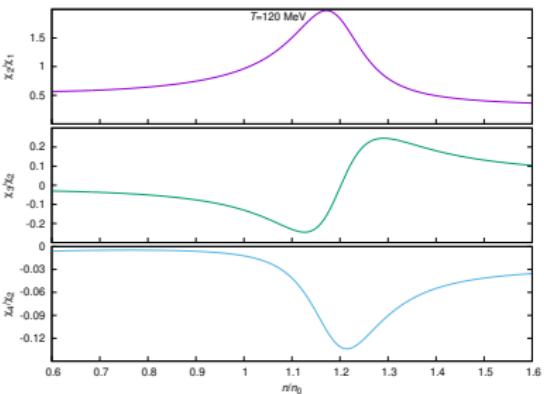

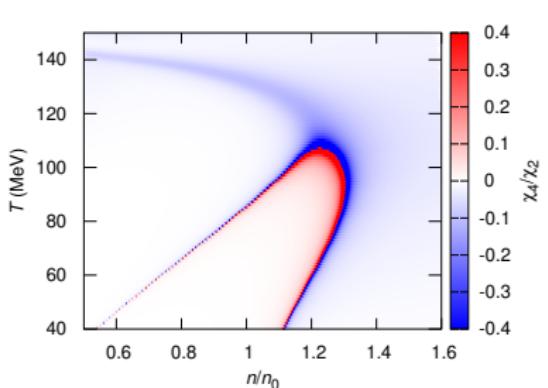

## Summary and outlook

- Nonequilibrium chiral dynamics describes entropy production
- FOPT dynamics leads to significant increase in  $S/A$
- Strong enhancement of  $\pi/p$  at onset of QCD phase transition
- Next: Dilepton production

(Savchuk, Motornenko, Steinheimer et al., arXiv:2209.05267)

# Susceptibilities near the critical point

- Phase diagram in  $T$ - $n_q$  plane
- Spinodal instabilities at  $T < T_{cp}$
- Diverging susceptibilities
