Scattering rate

- Scattering rate for a process $ij \rightarrow kl$ in the local rest frame of the fluid:

$$\Gamma_{ij\to kl}(E_1,T) = \frac{1}{16\pi^2 E_1^2} \int_{\frac{m^2}{2E_1}}^{\infty} dE_2 f_j(E_2,T) \int_{2m^2}^{4E_1E_2} ds [s\sigma_{ij\to kl}(s)].$$

- $f_j(E_2,T)$ is the thermal distribution: Bose-Einstein for gluons, Fermi-Dirac for quarks.
- Temperature T obtained from the hydrodynamical model.
- The regulation of the cross section:

$$\sigma_{ij \to kl}(s) = \frac{1}{16\pi s^2} \int_{-s+m^2}^{-m^2} dt \, |M|_{ij \to kl}^2, \, m = s_m g_s T = s_m \sqrt{4\pi \alpha_s} T.$$

Free parameters of the model: s_m, α_s .

J. Auvinen (JYFL, Finland)

Total scattering rate

The total scattering rate for a hard parton i is defined as

$$\Gamma_i = \sum_{j,(kl)} \Gamma_{ij \to kl}.$$

• The total scattering rate for a gluon:

Scattering rate

$$\Gamma_g = \Gamma_{gg \to gg} + \Gamma_{gg \to q\bar{q}} + \Gamma_{gq \to gq} + \Gamma_{g\bar{q} \to g\bar{q}}$$

• The total scattering rate for a quark q_i:

$$\begin{split} \Gamma_{q_i} = & \Gamma_{q_i g \to q_i g} + \Gamma_{q_i q_j \to q_i q_j} + \Gamma_{q_i q_i \to q_i q_i} \\ & + \Gamma_{q_i \bar{q}_i \to q_j \bar{q}_j} + \Gamma_{q_i \bar{q}_i \to q_i \bar{q}_i} + \Gamma_{q_i \bar{q}_i \to gg} \end{split}$$

The Monte Carlo simulation

- The hard parton is propagated in small time steps $\Delta t \sim {\cal O}(10^{-2})~{\rm fm}.$
- The probability for having (at least) one collision is $P(\text{number of collisions} \ge 1) = 1 e^{-\Gamma_i \Delta t}$.
- $\Gamma_i = \Gamma_i(E_1, T)$ is calculated in the local rest frame of the fluid \rightarrow boost $E_1, \Delta t$ to LRF.
- Finite scattering angles; non-eikonal propagation.
- After scattering, the parton with higher energy is selected as the hard parton \rightarrow Flavor change possible.
- The simulation ends when the temperature of the medium is low enough ($\approx 160~{\rm MeV}).$

The Answers

The contribution of elastic scatterings to energy loss of hard partons? With reasonable parameter values, elastic scattering would seem to give notable contribution to the suppression of high-energy hadrons. However...

The pathlength dependence of elastic energy loss?

This kind of fully incoherent model fails to reproduce the measured dependencies on the reaction plane angle and centrality.

The effect of initial state density fluctuations to energy loss?

The fluctuations average out in central collisions; they do seem to have small but clear effect on the nuclear modification in non-central case.

What next?

Implement also radiative energy loss and coherence effects. Photon production? Heavy quarks?

Extra slides

The effect of energy on quark scattering rate

Initial state

• Initial p_T distribution of the hard partons produced using CTEQ6L1 ⁸ parametrization for parton distribution functions $x_i f_i(x, Q^2)$:

$$\frac{d\sigma^{AA \to f+X}}{dp_T^2 dy_1} = \int dy_2 \sum_{ijk} x_1 f_{i/A}(x_1, Q^2) x_2 f_{j/A}(x_2, Q^2) \frac{d\sigma^{ij \to fk}}{dt}.$$

• The initial rapidity interval is chosen to be $|y_i| \le 1.0$.

⁸J. Pumplin, D. R. Stump, J. Huston, H. L. Lai, P. Nadolsky, W. K. Tung, JHEP 0207:012(2002), hep-ph/0201195

Extra slides

Initial state

• Starting point on xy-plane determined by sampling the nuclear overlap function

$$T_{AA}(\mathbf{b}) = \int d^2 \mathbf{s} T_A(\mathbf{s} + \mathbf{b}/2) T_A(\mathbf{s} - \mathbf{b}/2).$$

Nuclear density is given by Woods-Saxon distribution

$$n_A(r) = n_0(1 + e^{\frac{r - R_A}{d}})$$

with $n_0 = 0.17 \text{ fm}^{-3}$, $R_A = 1.12A^{1/3} - 0.86A^{-1/3} \text{ fm}$, d = 0.54 fm.

• The initial rapidity and the starting (proper) time τ_0 define the time $t_0 = \tau_0 \cosh(y_i)$ and z-coordinate $z_0 = \tau_0 \sinh(y_i)$.

The Monte Carlo simulation: Producing the thermal particle

The energy E_2 and the collision angle θ_{12} of the plasma particle are sampled from the expression of Γ as follows.

• The scattering rate for any particular process can be written in the form

$$\Gamma_X \sim \int_{\frac{m^2}{2E_1}}^{\infty} dE_2 f(E_2, T) (H(\frac{4E_1E_2}{m^2}) - H(2)),$$

where H(x) is the integral function of $\sigma_X(s)$ with the variable $x = \frac{s}{m^2} = \frac{2E_1}{m^2} E_2(1 - \cos \theta_{12})$. E_2 can be sampled from this expression.

• After E_2 has been found, the collision angle can be determined by picking a random number r from the interval $[H(2), H(\frac{4E_1E_2}{m^2})]$. Solving now x_0 from the equation $H(x_0) - r = 0$ gives $\cos \theta_{12} = 1 - \frac{x_0 m^2}{2E_1 E_2}$.

The Monte Carlo simulation: Scattering angle

The cross section of the process determines the distribution of scattering angle $\theta_{13}.$

- The scattering angle is determined in the CMS frame of the collision. The method is very similar to one used with finding the collision angle.
- The integral function is now $\Sigma_X(t) = \int dt |M|_X^2$. Picking a random number R from the interval $[\Sigma_X(-s+m^2), \Sigma_X(-m^2)]$ and solving t_0 from the equation $\Sigma_X(t_0) R = 0$ gives the scattering angle as $\cos \theta_{13} = \frac{2t_0}{s} + 1$.

Mixed phase (Central collisions)

- In the mixed phase, temperature stays constant $(T = T_C)$ while energy density ϵ keeps decreasing.
- The scattering rate Γ depends on T but not $\epsilon \to$ How to implement the effect of mixed phase?
- Effective temperature $T_{eff}(R,\tau) = \frac{30}{g_Q\pi^2}(\epsilon(R,\tau)-B)^{1/4}$ with bag constant $B = (239 \text{ MeV})^4$.
- The simulation ends when the boundary of mixed phase and hadron gas phase is reached (i.e. when $T < T_{\rm C}$).
